

Multi-Chain Portfolio Explorer — Flow

What happens from connecting a wallet to seeing a grouped portfolio.

Request flow (happy path)

Token normalization — "symbol alone isn't enough"

USDC on Ethereum and USDC on Base have *different* contract addresses. We assign both the same `assetId` (`usd-coin`) via a curated registry, so they collapse into one row when grouping by token. Native ETH across L2s shares `native:eth`. Unknown tokens fall back to `sym:SYMBOL@decimals` (decimals included so unrelated same-symbol tokens don't merge).

Failure & edge states

- empty No wallets tracked → prompt to connect / watch.
- loading Skeleton rows while the query is in flight.
- partial Some wallets fail → banner names them, successful wallets still render.
- mock No `ALCHEMY_API_KEY` → realistic mock data, badge shows "mock".
